Causal methods again, in detail

## Questions & review

- Questions?

## Questions & review

- Questions?
- Take away from workshop:
  - Need to think in a **broader way**
  - Do not stay fixated on a method
  - There's never a single solution/strategy

## Questions & review

- Questions?
- Take away from workshop:
  - Need to think in a **broader way**
  - Do not stay fixated on a method
  - There's never a single solution/strategy
- Key thing I'd like you to take from this course:  
learn how to **plan**, execution will come later

# Unit of analysis

# Unit of analysis

- **Level at which we have our observations**

→ Imagine you have an Excel spreadsheet with the data: each **row** indicates what?

# Unit of analysis

- **Level at which we have our observations**
  - Imagine you have an Excel spreadsheet with the data: each **row** indicates what?
- Deeply related to the variables we have
  - The UA is the level at which you are measuring your variables

# Unit of analysis

- **Level at which we have our observations**
  - Imagine you have an Excel spreadsheet with the data: each **row** indicates what?
- Deeply related to the variables we have
  - The UA is the level at which you are measuring your variables
  - Not all variables can be measured at the same level

# Unit of analysis

- **Level at which we have our observations**
  - Imagine you have an Excel spreadsheet with the data: each **row** indicates what?
- Deeply related to the variables we have
  - The UA is the level at which you are measuring your variables
  - Not all variables can be measured at the same level
  - Example: **cancer mortality**. At which levels can we measure this?

# Unit of analysis

- **Level at which we have our observations**
  - Imagine you have an Excel spreadsheet with the data: each **row** indicates what?
- Deeply related to the variables we have
  - The UA is the level at which you are measuring your variables
  - Not all variables can be measured at the same level
  - Example: **cancer mortality**. At which levels can we measure this?
- We can change the UA of a dataset (usually from bottom to top)
  - Example: let's say we have an individual-level dataset of diseases and outcome (death)

# Unit of analysis

Most important things:

- Be able to identify it
- **Choose the right unit of analysis** depending on the theory and mechanisms we are testing
  - Examples: democratic peace, trade flows

# Unit of analysis

Most important things:

- Be able to identify it
- **Choose the right unit of analysis** depending on the theory and mechanisms we are testing
  - Examples: democratic peace, trade flows
- How many variables and what's the unit of analyses in the next dataset?

## How many variables? Unit of analysis?

*Carte Figurative des pertes successives en hommes de l'Armée Française dans la Campagne de Russie 1812-1813.*  
 Dessiné par M. Minard, Inspecteur Général des Ponts et Chaussées en retraite.

Les nombres d'hommes perdus sont représentés par les longueurs des zones colorées à raison d'une millimètre pour six mille hommes; ils sont de plus écrits en lettres des zones. Le rouge désigne les hommes qui entrent en Russie; le noir ceux qui sortent. — Les renseignements qui ont servi à dresser la carte ont été pris dans les ouvrages de M. M. Chiers, de Léger, de Fessardat, de Chambray et le journal intime de Jacob, pharmacien de l'Armée depuis le 28 Octobre. Pour mieux faire juger à l'œil la diminution de l'armée, j'ai supposé que les corps de Prince Napoléon et du Maréchal Davout qui avaient été détachés aux Malibors et aux régions vers Orelcha et Wilejek, avaient toujours marché avec l'armée.

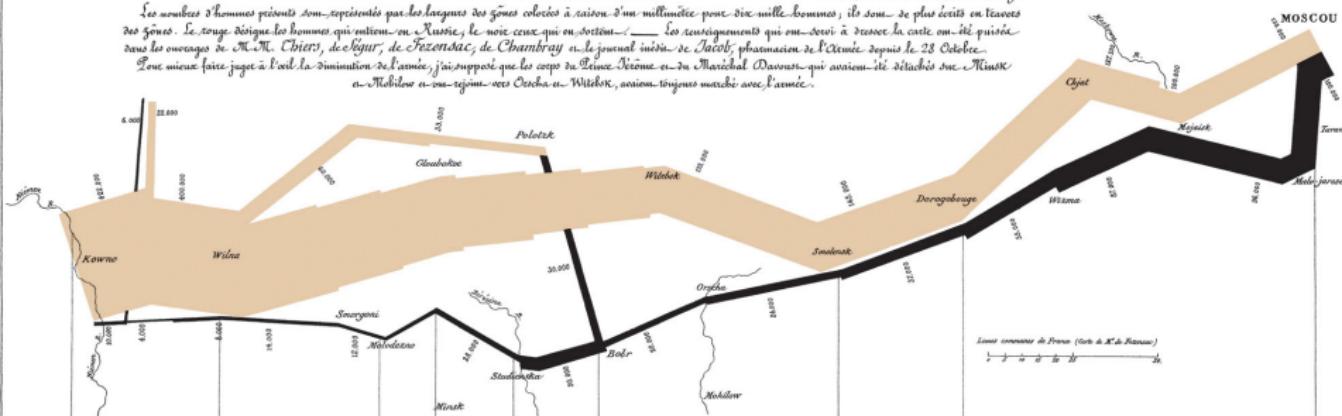

TABLEAU GRAPHIQUE de la température en degrés du thermomètre de Réaumur au dessous de zéro.

  - Internally valid studies, context-specific
  - Accumulating generalizable knowledge by repetition
  - 'Valid' studies and synthesis studies
  - Practice-oriented, Esther Duflo: 'The Economist as Plumber'
- What are we really learning? How much *knowledge* we gain?

# Generalizing results

- The Credibility Revolution in social sciences
  - Internally valid studies, context-specific
  - Accumulating generalizable knowledge by repetition
  - 'Valid' studies and synthesis studies
  - Practice-oriented, Esther Duflo: 'The Economist as Plumber'
- What are we really learning? How much *knowledge* we gain?
- Importance of meta-scientific knowledge
  1. Robustness of results and incremental science (→ meta-analyses)
  2. Generalization of results (→ construct and external validity)

# An example of a meta-analysis

- Effect of commodity prices on conflict
- What's the causal inference problem here?

## An example of a meta-analysis

- Effect of commodity prices on conflict
- What's the causal inference problem here?
- But there are options to solve this, right?

# An example of a meta-analysis

## **Do Commodity Price Shocks Cause Armed Conflict? A Meta-Analysis of Natural Experiments**

GRAEME BLAIR *University of California, Los Angeles*

DARIN CHRISTENSEN *University of California, Los Angeles*

AARON RUDKIN *University of California, Los Angeles*

**S**cholars of the resource curse argue that reliance on primary commodities destabilizes governments: price fluctuations generate windfalls or periods of austerity that provoke or intensify civil conflict. Over 350 quantitative studies test this claim, but prominent results point in different directions, making it difficult to discern which results reliably hold across contexts. We conduct a meta-analysis of 46 natural experiments that use difference-in-difference designs to estimate the causal effect of commodity price changes on armed civil conflict. We show that commodity price changes, on average, do not change the likelihood of conflict. However, there are cross-cutting effects by commodity type. In line with theory, we find price increases for labor-intensive agricultural commodities reduce conflict, while increases in the price of oil, a capital-intensive commodity, provoke conflict. We also find that price increases for lootable artisanal minerals provoke conflict. Our meta-analysis consolidates existing evidence, but also highlights opportunities for future research.

# An example of a meta-analysis

1. Literature review → 3,300 records

# An example of a meta-analysis

1. Literature review → 3,300 records
2. Look for similar research designs and topics:

“the 46 included studies (102 estimates) quantitatively analyze the effect of plausibly exogenous variation in world commodity prices on armed civil conflict by using a generalized difference-in-difference design with unit and time fixed effects”

# An example of a meta-analysis

1. Literature review → 3,300 records
2. Look for similar research designs and topics:

“the 46 included studies (102 estimates) quantitatively analyze the effect of plausibly exogenous variation in world commodity prices on armed civil conflict by using a generalized difference-in-difference design with unit and time fixed effects”

3. Make studies comparable → standardize coefficients

# An example of a meta-analysis

2. Look for similar research designs and topics:

“the 46 included studies (102 estimates) quantitatively analyze the effect of plausibly exogenous variation in world commodity prices on armed civil conflict by using a generalized difference-in-difference design with unit and time fixed effects”
3. Make studies comparable → standardize coefficients
4. Perform meta-analysis method

fixed-effects meta-analysis model & random effects m-a model

# Theoretical background on natural resources

H1: NR are the 'prize' to be won by fighting (+)

H2: Higher prices change opportunity cost (- for labor-intensive, + for capital-intensive)

H3: Lootable NR can be captured by fighting (+)

**TABLE 1. Commodity Classifications and Predicted Effect Direction from Each Hypothesis**

Commodity type	Characteristics		Predicted direction		
	Labor-intensive	Lootable	(H1)	(H2)	(H3)
Pooled (average of commodities)	Mix	Mix	+	+/-	+/0
Agriculture	✓		+	-	0
Artisanal minerals	✓	✓	+	-	+
Commercial minerals			+	+	0
Oil & gas		✓	+	+	+/0
Bundle of multiple types	Mix	Mix	+	+/-	+/0

## Meta-analysis findings

- **Pooling studies** across commodity types: no effect

## Meta-analysis findings

- **Pooling studies** across commodity types: no effect
- But when **disaggregating by commodity type**: effects coherent with theoretical predictions

# Meta-analysis findings

- **Pooling studies** across commodity types: no effect
- But when **disaggregating by commodity type**: effects coherent with theoretical predictions
  - price increases for **agricultural commodities** reduce the likelihood of armed conflict (labor-intensive commodities and opportunity cost)

# Meta-analysis findings

- **Pooling studies** across commodity types: no effect
- But when **disaggregating by commodity type**: effects coherent with theoretical predictions
  - price increases for **agricultural commodities** **reduce** the likelihood of armed conflict (labor-intensive commodities and opportunity cost)
  - price increases for **oil and gas** **increase** likelihood of conflict (capital-intensive commodity and returns to fighting)

# Meta-analysis findings

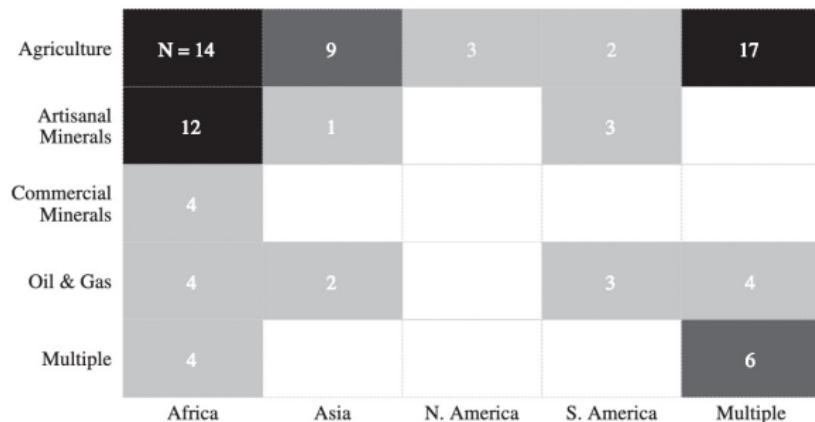

**FIGURE 1. Effects of Commodity Prices on Conflict by Commodity Type**

# Learning about gaps

- A meta-analysis can be used to identify **gaps**, e.g.
  1. **Spatial or temporal validity:** where and when do findings come from?
  2. **Publication bias:** are only positive findings being published?

**FIGURE 2. Evidence Gap Map (Number of Estimates) by Commodity Type and Continent**

# Generalizing results

- Meta-analyses are **not** enough
- We need some kind of formal approach to understand the validity of studies

# Generalizing results

- **Construct validity**: are we really measuring what we intent to?
  - is the treatment doing what we theoretically expect it to? and are we measuring the outcome correctly?
- **External validity**: would we get the same results if we replicate this in another context?
  - especially: temporal and spatial validity

## Construct validity

- This is about *mislabeled* the cause or outcome of a study
- We say we are analyzing the effect of  $X$  on  $Y$ , but are we really measuring that?

# Construct validity

- This is about *mislabeled* the cause or outcome of a study
  - We say we are analyzing the effect of  $X$  on  $Y$ , but are we really measuring that?
1. Construct validity of the **cause**: bundled treatments, exclusion restriction (assignment only affects through treatment), SUTVA, etc

# Construct validity

- This is about *mislabeled* the cause or outcome of a study
  - We say we are analyzing the effect of  $X$  on  $Y$ , but are we really measuring that?
1. Construct validity of the **cause**: bundled treatments, exclusion restriction (assignment only affects through treatment), SUTVA, etc
  2. Construct validity of the **outcome**: similar, making sure the empirical measure mirrors the theoretical construct

## External validity (Egami and Hartman 2023)

- This is about understanding the *conditions* under which  $X \rightarrow Y$   
(it is very unlikely that the effect takes place under universal conditions)

## External validity (Egami and Hartman 2023)

- This is about understanding the *conditions* under which  $X \rightarrow Y$   
(it is very unlikely that the effect takes place under universal conditions)
- ‘Effect-generalization’ and the softer ‘sign-generalization’

# External validity (Egami and Hartman 2023)

- This is about understanding the *conditions* under which  $X \rightarrow Y$   
(it is very unlikely that the effect takes place under universal conditions)
- ‘Effect-generalization’ and the softer ‘sign-generalization’
- Different types of external validity:
  - Populations ( $X$ -validity)
  - Treatments ( $T$ -validity)
  - Outcomes ( $Y$ -validity)
  - Contexts and settings ( $C$ -validity)

**TABLE 1. Summary of Typology**

	Practical concerns (examples)	Causal assumptions (formalization)
X-validity	Convenience samples, survey non-response, attrition	Ignorability of sampling and treatment effect heterogeneity (Assumption 1)
T-validity	Realistic treatments, bundled treatments, difference in implementations	Ignorable treatment variations (Assumption 2)
Y-validity	Behavioral or hypothetical survey outcomes, short- or long-term outcomes	Ignorable outcome variations (Assumption 3)
C-validity	Mechanisms differ across time, geography, political institutions, and so on	Contextual exclusion restriction (Assumption 4)

## The special case of *temporal validity*? (Munger 2023)

- Blind spot in incremental-knowledge model of causal empiricism

## The special case of *temporal validity*? (Munger 2023)

- Blind spot in incremental-knowledge model of causal empiricism
- One of the goals of social science: prediction (in order to act)

## The special case of *temporal validity*? (Munger 2023)

- Blind spot in incremental-knowledge model of causal empiricism
- One of the goals of social science: prediction (in order to act)
- Problem of knowledge decay : dependent on rate of change  $r$ 
  - “All of the knowledge contained in published papers comes from the past, and all action is in the future”

## The special case of *temporal validity*? (Munger 2023)

- Blind spot in incremental-knowledge model of causal empiricism
- One of the goals of social science: prediction (in order to act)
- Problem of knowledge decay : dependent on rate of change  $r$ 
  - “All of the knowledge contained in published papers comes from the past, and all action is in the future”
- The problem is that, depending on the topic or realm of study,  $r$  might be too large

# The special case of *temporal validity*? (Munger 2023)

- Blind spot in incremental-knowledge model of causal empiricism
- One of the goals of social science: prediction (in order to act)
- Problem of knowledge decay : dependent on rate of change  $r$ 
  - “All of the knowledge contained in published papers comes from the past, and all action is in the future”
- The problem is that, depending on the topic or realm of study,  $r$  might be too large
- Existing approaches use the idea of treatment  $\times$  covariate space to know where and to what extent we can generalize, but under certain conditions, the problem is that that space *changes or expands*
  - Example of studies on dissent and the Arab Spring & importance of smartphones

# The special case of *temporal validity*? (Munger 2023)

- Blind spot in incremental-knowledge model of causal empiricism
- One of the goals of social science: prediction (in order to act)
- Problem of knowledge decay : dependent on rate of change  $r$ 
  - “All of the knowledge contained in published papers comes from the past, and all action is in the future”
- The problem is that, depending on the topic or realm of study,  $r$  might be too large
- Existing approaches use the idea of treatment  $\times$  covariate space to know where and to what extent we can generalize, but under certain conditions, the problem is that that space *changes or expands*
  - Example of studies on dissent and the Arab Spring & importance of smartphones
- How do we solve this? Importance of qualitative studies and theory

Questions

Causal methods again, in detail

# Synthetic control methods

- Imagine combining diff-in-diff with matching
  - treatments goes into effect at one time, and only affects one group
  - you can use pre-T data to make control and treated comparable
  - you estimate effect from post-T divergence

# Original study

## The Economic Costs of Conflict: A Case Study of the Basque Country

By ALBERTO ABADIE AND JAVIER GARDEAZABAL\*

*This article investigates the economic effects of conflict, using the terrorist conflict in the Basque Country as a case study. We find that, after the outbreak of terrorism in the late 1960's, per capita GDP in the Basque Country declined about 10 percentage points relative to a synthetic control region without terrorism. In addition, we use the 1998–1999 truce as a natural experiment. We find that stocks of firms with a significant part of their business in the Basque Country showed a positive relative performance when truce became credible, and a negative relative performance at the end of the cease-fire. (JEL D74, G14, P16)*

*American Economic Review, 2003*

Questions

Causal methods again, in detail

## Controlling in regression

- We probably already know this
- We've seen what it means controlling: just adjusting for the variation already predicted by the other variables
- One limitation though: we need to *observe* those variables

# Controlling

- We are going to see two further methods of controlling widely used:
  - Matching
  - Fixed effects

# Matching

- Adding control variables is not the only way to control / close back doors
- Imagine we have the following model:
  - $Z \rightarrow X \rightarrow Y \leftarrow Z$
  - Where  $Z$  is whether someone is retired or not
- If we select a sample of *only* retired people, we are closing that back door
  - $(X \leftarrow Z \rightarrow Y)$
- Matching is something like this, it's basically about creating groups of comparison where  $Z$  (which can be several variables) does not vary

# How matching works

- We have a treatment group and a control group (so: *binary* treatment variables)
- The main idea: give different *weights* to treated and control observations, so we eliminate
- We get these weights by using one or more *matching variables* (i.e. confounding variables)

# How matching works

- Imagine we have:
  - Treatment: get some specific skill training
  - Outcome: get a job afterwards
  - Confounding variable: gender
- Control group: 80 men and 20 women
  - 75% of men get a job, 60% of women do
- Treatment group: 500 men and 500 women
  - 70% of men get a job, 55% of women do
- Comparing within each group, we know the treatment effect is a 5% increase in the odds of getting a job ( $70 \rightarrow 75$ ,  $55 \rightarrow 60$ )
- But if we do the global comparison, it's almost 10%
  - $60 \text{ men} + 12 \text{ women out of } 100 = 72/100 = 72\%$ , vs  $(350 + 275)/1000 = 62.5\%$ , so a difference of 9.5 points

## How matching works

- The problem is we have 4 times more men in the treated group than women, whereas we have equal proportion on the control group
- So we'll weight the control observations by gender, giving *more* weight to the men observations, so it looks more similar to the treatment group
- $(4 * 350 + 1 * 275) / (4 * 500 + 1 * 500) = 67\%$
- Now, the unweighted difference in the treatment group was 72%, and now the weighted difference in the control group is 67%
- The difference is 5 points, the same as the within-group calculation we did before

# Two approaches to matching

## 1. Distance matching

- We want to create a dataset where treatment and control observations have similar values (distance) in the confounding variables
- If, say, our confounding variable is income, we'll pick control observations that have a similar value on income to each of the treatment observations
- <https://nickchk.com/causalgraphs.html>

# Two approaches to matching

## 1. Distance matching

- We want to create a dataset where treatment and control observations have similar values (distance) in the confounding variables
- If, say, our confounding variable is income, we'll pick control observations that have a similar value on income to each of the treatment observations

- If, say, our confounding variable is income, we'll pick control observations that have a similar value on income to each of the treatment observations
- <https://nickchk.com/causalgraphs.html>

# Two approaches to matching

## 2. Propensity score matching

- We want to account for the differential likelihood in getting into treatment depending on the value of the confounding variables
- We estimate the probability of getting into treatment, usually by doing a regression where the outcome is the treatment and the right-hand variables are the confounders
- We control for the propensity score matching, or select based on it (or both)

# Two approaches to matching

## 2. Propensity score matching

- We want to account for the differential likelihood in getting into treatment depending on the value of the confounding variables
- We estimate the probability of getting into treatment, usually by doing a regression where the outcome is the treatment and the right-hand variables are the confounders
- We control for the propensity score matching, or select based on it (or both)

# Two approaches to matching

## 2. Propensity score matching

- We control for the propensity score matching, or select based on it (or both)

## Two approaches to matching: propensity score

```
df = data.frame(  
    treat = c(rep(1, 100), rep(0, 1000)),  
    gender = c(rep("M", 80), rep("F", 20), rep(c("M","F"), each = 500)),  
    y = NA  
)  
  
df$y[df$treat == 1 & df$gender == "M"] = rbinom(80, 1, 0.75)  
df$y[df$treat == 1 & df$gender == "F"] = rbinom(20, 1, 0.6)  
df$y[df$treat == 0 & df$gender == "M"] = rbinom(500, 1, 0.7)  
df$y[df$treat == 0 & df$gender == "F"] = rbinom(500, 1, 0.55)  
  
m1 = glm(y ~ treat, data = df)  
m2 = glm(y ~ treat + gender, data = df)  
modelsummary(list(m1, m2))  
  
ps = glm(treat ~ gender, data = df)  
df$propensity_score = predict(ps, newdata = df)  
m3 = glm(y ~ treat + propensity_score, data = df)  
modelsummary(list(m1, m2, m3))
```

## Two approaches to matching: propensity score

Num.Obs.	1100	1100	1100

## Matching vs regression

- Matching and regression are complementary approaches
- e.g. regression doesn't waste any information, but has a linearity assumption
- It's usual to use both at the same time

## Fixed effects

- The problem with covariate adjustment, regardless of whether we use regression or matching, is that we need to *observe* those variables
- But another strategy when we have unobserved confounders is to try within-group comparisons, which will work when the unobserved variance is contact within some group
- For example, imagine cases when our  $U$  variable is:
  - *Country history*, in a cross-national analysis
  - *City of origin*, in an individual-level analysis
  - *Individual background*, in a panel survey analysis
  - *Company effects*, if we look at the effects of English courses on internal promotion using individual data from many different companies
  - etc

# Difference-in-differences

- Treatments usually occur at a particular moment in time, e.g.:
  - Minimum wage increase
  - Terrorist attack
  - Influx of refugees
  - ...
- In those cases, if we have before & after observations, we have something like this:

- The **problem** is that **all** the variation goes through time, so if we close that back door, we're left with nothing

# Difference-in-differences

- So one strategy we can use is to bring additional group that is *not treated* and for which we also have before/after observations
  - Minimum wage increase: maybe those earning above MW?
  - Influx of refugees: other countries? regions far from the border?
  - Terrorist attack: do we have a control (untreated) group?
  - ...

# Difference-in-differences

- We can compare changes across time *within* the treated and control groups (closing the back door through group)
- Compare within-group variation between treated and control (since time affects both ‘within-variations’ the same way, we are closing the other back door through time)

## Difference-in-differences

- You can estimate this effect just with group means
- But it is often easier to use regression, also because you can include controls:

$$Y_{it} = \beta_0 + \beta_1 Treated_i + \beta_2 After_t + \beta_3 (Treated_i \times After_t) + \beta^\top x_i + \epsilon_{it} \quad (1)$$

- But why do we need all this?

# Difference-in-differences

- Because DiD identification **depends** on the assumption that the **control group is a good counterfactual to the treated group**

- One way to test this is checking if the **parallel trends assumption** holds (we need data further back in time)

## DiD example

## The Political Salience of Cultural Difference: Why Chewas and Tumbukas Are Allies in Zambia and Adversaries in Malawi

DANIEL N. POSNER *University of California, Los Angeles*

This paper explores the conditions under which cultural cleavages become politically salient. It does so by taking advantage of the natural experiment afforded by the division of the Chewa and Tumbuka peoples by the border between Zambia and Malawi. I document that, while the objective cultural differences between Chewas and Tumbukas on both sides of the border are identical, the political salience of the division between these communities is altogether different. I argue that this difference stems from the different sizes of the Chewa and Tumbuka communities in each country relative to each country's national political arena. In Malawi, Chewas and Tumbukas are each large groups vis-à-vis the country as a whole and, thus, serve as viable bases for political coalition-building. In Zambia, Chewas and Tumbukas are small relative to the country as a whole and, thus, not useful to mobilize as bases of political support. The analysis suggests that the political salience of a cultural cleavage depends not on the nature of the cleavage itself (since it is identical in both countries) but on the sizes of the groups it defines and whether or not they will be useful vehicles for political competition.

# Regression discontinuity

**FIGURE 1. Research Sites**

# Regression discontinuity

- RDD works well when assignment into treatment depends on a cutoff along a **running variable**
  - Do incumbent politicians have an electoral advantage? (vote share)
  - What is the effect of being drafted into the military? (birth year)
  - Effect of national policies in ethnic identification in Africa? (distance to colonial borders)
- This is the source of the exogenous variation (or if you will, the natural experiment):
  - Although many variables confound the relationships between  $X$  and  $Y$ , nothing should be too different *around the cutoff* between treatment and control groups (local randomization assumption)
  - Sometimes you look at different *bandwidths* to check this

# RDD

## Economic Shocks and Civil Conflict: An Instrumental Variables Approach

---

Edward Miguel

*University of California, Berkeley and National Bureau of Economic Research*

Shanker Satyanath and Ernest Sergenti

*New York University*

Estimating the impact of economic conditions on the likelihood of civil conflict is difficult because of endogeneity and omitted variable bias. We use rainfall variation as an instrumental variable for economic growth in 41 African countries during 1981–99. Growth is strongly negatively related to civil conflict: a negative growth shock of five percentage points increases the likelihood of conflict by one-half the following year. We attempt to rule out other channels through which rainfall may affect conflict. Surprisingly, the impact of growth shocks

### Abstract

Weak state capacity is one of the most important explanations of civil conflict. Yet, current conceptualizations of state capacity typically focus only on the state while ignoring the relational nature of armed conflict. We argue that opportunities for conflict arise where relational state capacity is low, that is, where the state has less control over its subjects than its potential challengers. This occurs in ethnic groups that are poorly accessible from the state capital, but are internally highly interconnected. To test this argument, we digitize detailed African road maps and convert them into a road atlas akin to Google Maps. We measure the accessibility and internal connectedness of groups via travel times obtained from this atlas and simulate road networks for an instrumental variable design. Our findings suggest that

## Alternative approaches to IV: build your own

### *Instrumental Variable Approach*

We complement our robustness checks with an instrumental variable (IV) strategy that addresses potential omitted variable biases not captured by the previous tests. In particular, there might be hitherto unmeasured group-level characteristics that have affected colonial road building and recent conflict. To address such endogeneity as well as potential systematic measurement bias in the Michelin maps, our IV approach exploits variation from road networks simulated on the basis of countries' population distribution. Our IV approach improves identification by isolating the component of RSC that is due to the spatial population distribution within a country. While population distributions are less malleable than road networks, populations are not randomly distributed. We must therefore rely on the assumption that the population distributions that produce our simulated road networks are conditionally exogenous to conflict. We address potential violations of this assumption below.

## Alternative approaches to IV: build your own
